

1. The first step is to identify the variables that are being measured. In this case, the variables are the number of people who are employed, the number of people who are unemployed, and the total number of people in the labor force.

2. The second step is to determine the units of measurement for each variable. The units of measurement are the number of people, which is typically measured in millions.

3. The third step is to collect data for each variable. This can be done by using a survey or by using data from a government agency.

4. The fourth step is to analyze the data. This can be done by calculating the unemployment rate, which is the number of unemployed people divided by the total number of people in the labor force.

5. The fifth step is to interpret the results. This can be done by comparing the unemployment rate to the unemployment rate in other countries or to the unemployment rate in previous years.
